Two table properties anticipate the accuracy lost on new pairs

From the yield table, before modelling

Between-pair share

$\Sigma_p\, n_p(\bar{y}_p - \bar{y})^2 \,/\, \Sigma_i (y_i - \bar{y})^2$

how much of the yield follows the pair

Pairing sparsity

$(n_1 + n_2 - 1) / n_{\text{pairs}}$

substrate levels per measured pair;
high when substrates have few partners

R² lost on new pairs
